Finding	Design decision
Corrections change the component in 65.2% of FAA-recorded pairs	Represent `SUPERSEDES` explicitly; down-weight superseded records in the ranking (factor 0.3); show the corrector next to a corrected record
Exhaustive pairing is quadratic	Only compare within the same aircraft, only with earlier records, only when at least one matching signal exists, at most 25 candidates
Models disagree and fail	Ranking is deterministic and needs no model; the model only phrases it; failures are reported, not hidden
Model-generated identifiers can be invented	Every identifier in the text is checked against the graph; unmatched ones are marked unverified
Analysis is expensive and rate-limited	Ingest stores records as unanalysed; analysis is a separate, resumable, budgeted step; the interface shows "Not analysed" honestly
Labels come free from the data	Use FAA-recorded supplemental pairs as ground truth rather than hand labels
